Introduction
Sclerosing Angiomatoid Nodular Transformation (SANT) of the spleen is a rare benign lesion of the spleen with unknown etiology. Since it was first defined in 2004, a total of 135 cases of SANT have been reported in the English literature. SANT is classically considered to be a female-predominant disease, with most of the patients in the 30- to 60-year age group. Most lesions are found incidentally on imaging, the differential diagnosis from other splenic tumors or malignant lesions is very difficult. A splenectomy is required and the diagnosis is based on pathological analysis.

Case report
A 73-year-old female presented with vague abdominal pain. Laparoscopic splenectomy was performed for the splenic mass. Immunostaining of the excised specimen revealed 3 distinct types of vessels in the angiomatoid nodules: CD34−/CD8−/CD31+ small veins, CD34−/CD8+/CD31+ sinusoids, and CD34+/CD8−/CD31+ capillaries, leading to the diagnosis of SANT of the spleen.

Conclusion
We report a new case of SANT, with emphasis on the differential diagnosis and pathogenesis of SANT with review of the literature.
